1. Introduction

“The notion of ‘software engineering’ was first proposed in 1968” (Somerville, 2011). Ever since the profession started software projects have become bigger and more complex. This is because the hardware has been growing even faster and so software engineers have been having a hard time keeping the increasing phase up (Frederick and Brooks, 1987). The increasing code complexity raises new problems with understanding existing code and increases probability of software flaws. Software complexity can be later decreased by refactoring code. Refactoring can mean e.g. removing duplicate code by abstraction or renaming and commenting code to make it more readable.

Software metric is a quantitative value calculated from a piece of code or even a whole software project. The magnitude of the metric does not matter. We are more interested about the change of the metric over a defined amount of time. One of the main reasons to implement software measurements for projects is to replace reviews with metrics to define software quality. Tracking the quality of software makes it easier to plan and budget well beforehand which makes the software more profitable.

ABB Drives manufactures industrial drives which are controlled by software. Drives are made to last for a long period of time and the same goes for the software inside the machine. Also new bugs are found and customers demand new features which makes the software evolve rapidly over time. The same effect that Brooks discovered over 30 years ago something that still exists in companies: software size and complexity increases over time. Without refactoring the software may become somewhat useless and understandable for the developers. Also if we spend too much time refactoring and improving the code, no new features gets developed and customers are left unsatisfied. In a big company it is hard to perceive the whole picture and so the happy medium of internal improving and

development can be hard to find.

First the reader will get familiarized with the underlying theory of software metrics. Furthermore a part of the task is also to determine the core metrics by getting familiar with the most commonly used metrics and make conclusions. Later thesis tries to solve a small part of this problem and guide the development teams to the right direction by introducing a systematic software analysis. Analysis calculates different core software metrics and ideally represents a long-term graph to determine whether the quality of the software is increasing or decreasing and how rapid is the change.

The ultimate goal of this thesis is to help the company's software development teams to decide when to refactor code and improve tools and dependencies and how much time should be used for it.

2. Theory behind software metrics
